

**(Proof) Either a graph or its complement is connected.**

Tim initially motivated this proof — here I go through the proof with an eye towards highlighting how strengthening the statement is helpful.

**The Proof**

We want to prove that if  $G$  is not connected, then the complement of  $G$  is connected.

So, we know we have two vertices  $u$  and  $v$  in  $G$  with no path between them.

Here comes the main idea: we know there’s no path at all in  $G$  between  $u$  and  $v$ , but let’s **weaken that assumption** (and therefore **strengthen the statement**):

- instead of assuming there is *no path of any length* between  $u$  and  $v$ ...
- ...let’s assume there is *no path of length 1 or 2* between  $u$  and  $v$ .

This weakening, as of now, is completely unmotivated. (Another way to do this proof involves strengthening the target instead, from  $G$  is connected to  $G$  is connected with diameter at most 3. But I just focus on this weakening here.)

Now, we know that for any vertex in  $G$ , it may be a neighbour to  $u$  in  $G$ , and it may be a neighbour of  $v$  in  $G$ , but it can’t be a neighbour of both  $u$  and  $v$  in  $G$  (or else there will be a path of length 2 in  $G$  between  $u$  and  $v$ ).

So, now we want to prove that in  $G^c$ , any two vertices  $x$  and  $y$  are connected by a path.

- We know  $u$  and  $v$  aren’t neighbours in  $G$ , so they are neighbours in  $G^c$ .

- We also notice that  $x$  can’t be neighbours with both  $u$  and  $v$  in  $G$ , so it’s non-neighbours with at least one of them in  $G$ , so it’s neighbours with at least one of them in  $G^c$ .

- Likewise,  $y$  is neighbours with at least one of  $u$  and  $v$  in  $G^c$ .

- So,  $x$  connects to the  $u$ - $v$ -connected-component, which connects to  $y$ .

So,  $x$  and  $y$  are connected in  $G^c$ .  $\square$
